

Week 2: HTML5 & CSS3 Basics

1. Basic HTML Tags, Attributes, Forms, Semantic Elements

HTML5 is the foundation of web development and is used to structure web pages. Basic HTML tags such as headings, paragraphs, links, images, and lists help organize content properly. Attributes provide extra information to elements, such as source links and identifiers. Forms are used to collect user input like text, passwords, and selections. Semantic elements such as header, footer, section, and article improve code readability and make websites more accessible and SEO-friendly.

2. CSS Syntax, Selectors, Classes, IDs

CSS3 is used to style and design web pages. CSS syntax includes selectors, properties, and values that define how elements appear on the screen. Selectors help target specific elements, while classes and IDs allow customized styling for single or multiple elements. Understanding these basics is important for writing clean and reusable stylesheets.

3. Styling Web Pages

Styling web pages with CSS makes websites visually attractive and user-friendly. Developers can change backgrounds, spacing, alignment, borders, and layouts to improve appearance. Proper styling ensures a professional look and improves user experience by making content easy to read and navigate.

4. Applying Colors, Fonts, Box Model

Colors and fonts play an important role in website design by improving readability and branding. CSS allows developers to customize text styles, sizes, and font families. The box model explains how margin, border, padding, and content work together to define spacing and layout.

Understanding the box model is essential for designing structured and responsive web pages.

Conclusion

This week focused on learning HTML5 and CSS3 basics, which are essential for creating structured and visually appealing websites. These concepts provide the foundation for frontend development and responsive web design.
